Artificial Model Building

(searching for dispersed signals in the LHC search results)

Disclaimer

What I wish to present here, is a proof of principle, no more.

(But hey, I will show running code, that mostly doesn't crash!)

The bigger philosophy behind this goes as follows:

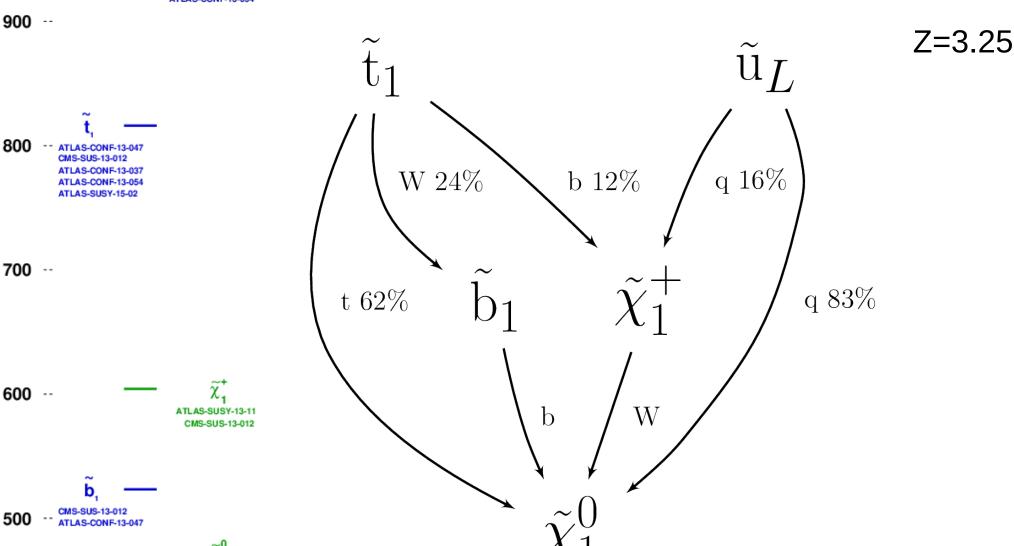

We have all these hundreds of wonderful LHC results (simplified models results, to be more concrete). Not to mention non-LHC data.

Let's maximally combine results and data-mine and machine-learn the sh*t out of them!

TLAS-SUSY-16-07 CMS-SUS-13-012 ATLAS-CONF-13-047 ATLAS-CONF-13-054

1000--

Signal strength multipliers: $\tilde{u}_L = 0.88, \tilde{b}_1 = 1.22, \tilde{t}_1 = 0.74, \tilde{\chi}_1^+ = 1.03$ Contributions by particles: $\tilde{u}_L = 0.76, \tilde{t}_1 = 0.72, \tilde{\chi}_1^+ = 0.08, \tilde{b}_1 = 0.15$

```

 Consider that we combine the respective topologies and analyses listed on the left, and treat it as a single BSM model with an overall signal strength μ as the only free parameter. Testing for compatibility with the Standard Model results in a test statistic Z (significance) of 3.25.

1000 --Where does the significance Z come from? 900 --`- ATLAS-SUSY-2015-02:SR1 (EM, T2tt) nobs: 12, nbg: 5.5 +/- 0.72 `- ATLAS-SUSY-2016-07:2j_Meff_1200 (EM, T2) nobs: 611.0, nbg: 526.0 +/- 31.0 800 `- ATLAS-CONF-2013-037:SRtN3 (EM, T2tt) nobs: 7, nbg: 5.0 +/- 2.0 `- ATLAS-CONF-2013-047:A Medium (EM, T2*) nobs: 135, nbg: 122.0 +/- 18.0 `- ATLAS-CONF-2013-054:8j50 flavor 0 b-jets (EM, T2*) 700 -nobs: 40, nbg: 35.0 +/- 4.0 `- ATLAS-SUSY-2013-11:WWc-DF (EM, TChiWW) nobs: 11, nbg: 9.0 +/- 2.2 many) nobs: 32, nbg: 22.8 +/- 5.2

How was this model constructed?

How was this model constructed?

Two new components on top of SModelS:

- An analysis combiner algorithm that finds the optimal "legal" combination of analysis results.
- In this talk, "optimal" means "maximizing the significance Z while evading all exclusions". Other criteria can however be employed (finding BSM models that are interesting in a different way).
- Different choices of what are "legal" combinations are possible. In this talk I am using "aggressive" combination: signal regions must be clearly distinct. Control regions are ignored.
- A "model builder" that randomly constructs BSM models in a Metropolis-Hastings-like fashion.
- The walker starts from the Standard Model
- It may randomly introduce and "kill" BSM particles.
- It may randomly change masses of particles.
- It may randomly change branching ratios.
- The cross section is computed as if it were a SUSY model. However, the walker may randomly change particle-specific signal strength modifiers that are applied to the computed cross sections.
- A neural network the learns to predict the "score" of the combiner, and then uses the gradient of the score instead of a random step may speed things up.

Combination of analyses

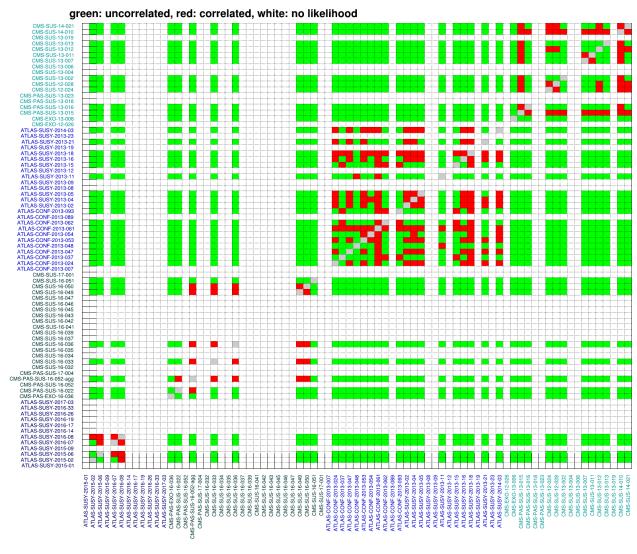

Joint likelihoods for combining analyses

many pairs of analyses can be treated as approximately uncorrelated in the "aggressive combination" scheme (the green blocks, think e.g. of a 8 TeV ATLAS result and a 13 TeV CMS result)

Started a Les Houches project to systematically study correlations

between analyses:

Correlations between analyses, combination strategy: ,,aggressive"

https://phystev.cnrs.fr/wiki/2019:groups:tools:correlations

Combination of analyses

The Z score

- finds optimal combinations of analyses, combinability given by matrix in slide before
- if a result can be added to a combination, it has to be added.
- will implement different criteria for what is considered "optimal". In this talk, optimal means, it finds the combination that maximally falsifies the standard model hypothesis in a likelihood ratio test.

$$T = -2\ln\frac{\mathrm{H_{SM}}}{\sup\{\mathrm{H_{BSM}}(\mu) : \mu \in \mathbb{R}^+\}}, Z = \sqrt{T}$$

So we optimize for the test statistic of the hypothesis test, where the standard model is the null hypothesis and the BSM model is the alternative hypothesis with an overall signal strength multiplier as the only free parameter. That way Neyman-Pearson Lemma holds, at least in principle, as μ =0 gives the Standard Model. Since I search for models that maximize T, I do not compute a p value, as it would be misleading. One should refrain from giving the test statistic a probabilistic meaning. In the next iteration I will want to replace it with a Bayes factor.

 All models have to evade all exclusions of all results in the SModelS database (though I relaxed the requirement a bit since strictly speaking we are "allowed" to violate one out of twenty 95% exclusions).

Houston, we have a problem!

(once we have expected upper limits, we are in the business. give us efficiency maps and we can go to the moon)

Second new SModelS ingredient: model builder

- currently a Metropolis-Hastings-type random walk in the space of all models that can be described with semantically correct SLHA files (actually currently only a subset).
- in the future will want to try a neural network that learns "Z". Should be faster, as long was we want only central values, and not complete distributions.
- We begin with the standard model, all BSM particles being "frozen out" (put to high masses). We then take random steps in model space.
 Possible random steps:
 - freezing a particle out
 - unfreezing a particle
 - changing a particle's mass
 - · changing a particle's branchings
 - changing a particle's signal strength modifier (we use the NLO SUSY cross sections for defaults)
- All models need to obey all (relaxed)
 SModelS exclusions. So both antagonists
 (the "excluder" and the "excess finder")
 experience the same biasses
 from the incomplete SModelS database.
- We can punish the algorithm for introducing new particles.

Ach, come on – it's just a game!

Loosely speaking, we can think of it as a game, in the game-theoretical sense. Played between the algorithm that tries to exclude the model ("excluder", "experimentalist"), and the algorithm that tries to build a model that maximally violates the Standard Model hypothesis ("builder", "theorist").

$$\hat{M} \equiv \underset{M:\text{models}}{\operatorname{argmax}} Z(M) | \underset{i:\text{results}}{\operatorname{max}} (r_i(M)) \le 1$$

r_i: predicted signal strength / experimental upper limit, for the result (combination) "i"

(Ok, ok, I guess one could also think of it as "optimization with constraints". But that sounds so much less cool.)

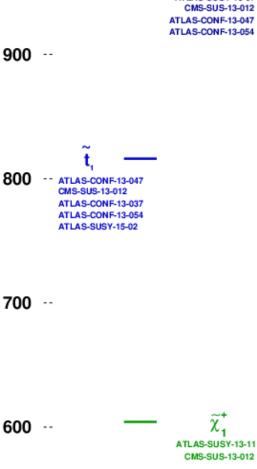

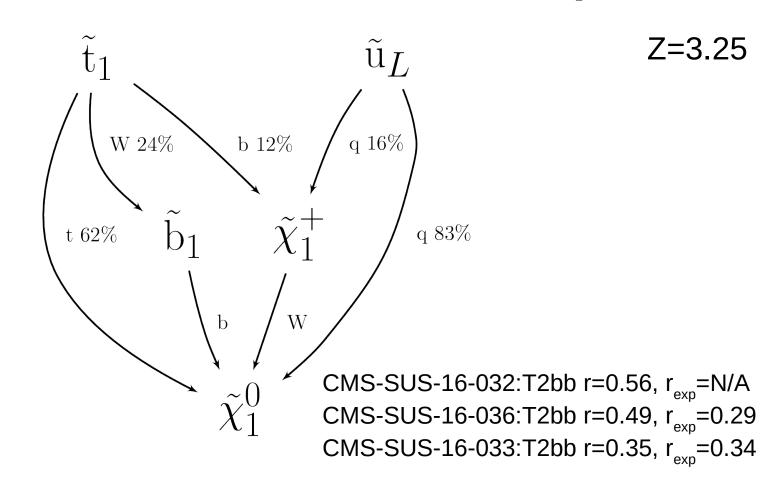

To repeat: this is what the algorithm found after O(100) steps

ATLAS-SUSY-16-01

Transpose Add LeakyRelu Transpose MatMul LeakyRelu MatMul Add Sigmoid

To Do

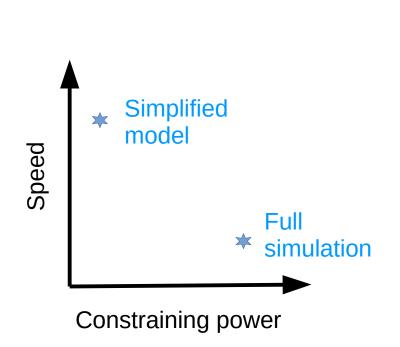

- Try learning different criteria, e.g. most "spectacular" signatures that miraculously evade all SMS constraints.
- Train a neural network that predicts the objective function (e.g. the significance Z for the builder, r_{max} for the excluder) \rightarrow differentiable function, should make for much faster convergence (as long as we only want central values)
- Add the most recent results (CMS, what shall we do?)
- Allow also for displaced signatures (widths as free parameters? computed widths?) [SModelS 2.0.0]
- Constraints from measurements may be added via likelihoods on Wilson coefficients.
- Compute the distribution of the test statistic T under the Standard Model assumption.
- SModelS actually gives much more detailed feedback than just a single test statistic. Make use of it.
- Long term vision: to have a full, real sample of a posterior in model space.
- Can we / should we move from SLHA files to arbitrary Lagrangians (described eg as UFO or Sarah files)?

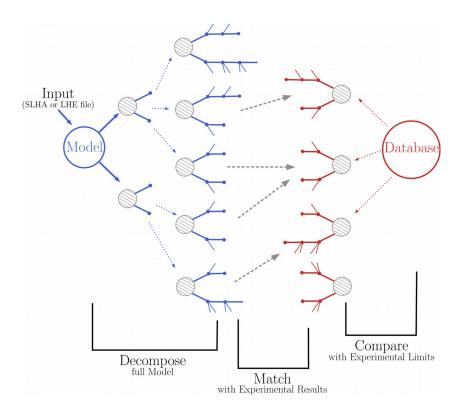

Backup

Recap: the Idea behind SModelS

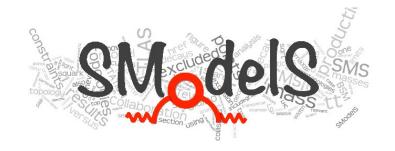

SModelS confronts theories beyond the Standard Model (BSM) with LHC search results by decomposing full models into their simplified models topologies, and comparing the cross section predictions of these individual topologies with a database of SMS results.

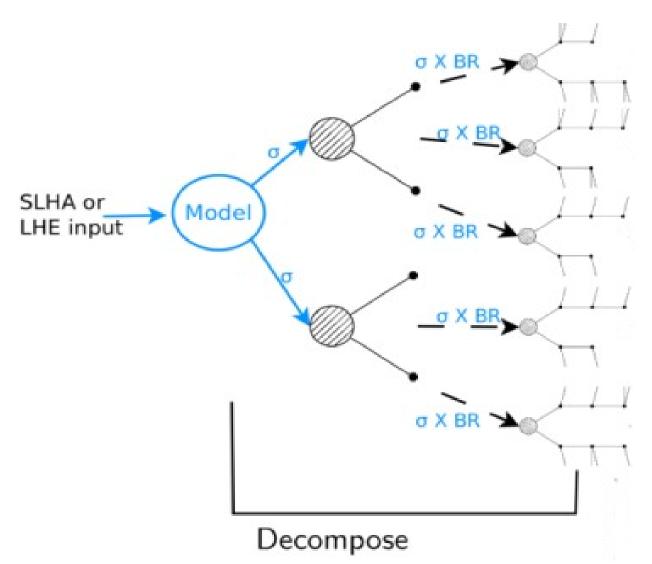

Recap: How SModelS works

1) Decomposition of a fundamental model

Input: SLHA file (mass spectrum, BRs) or LHE file (parton level)

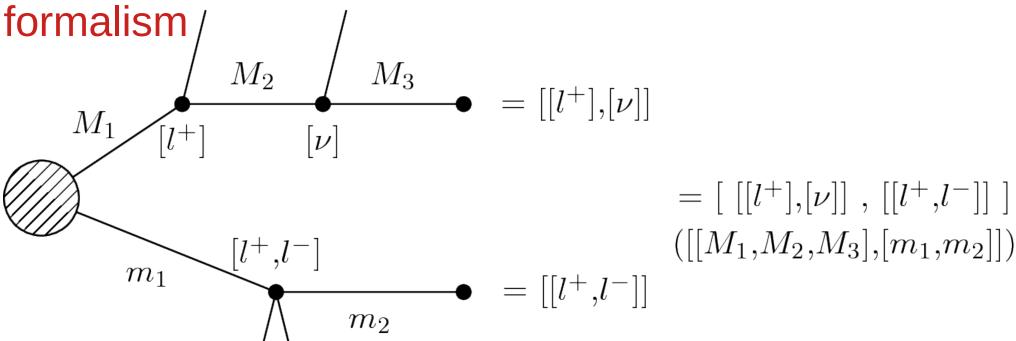

Currently the model must have a \mathbf{Z}_2 symmetry

The decomposition produces a set of simplified model topologies (dubbed "elements")

Recap: How SModelS works

2) Description of the topology in the SModelS

Each topology is described by:

- Topology shape + final states
- BSM masses
- $\cdot \sigma x BR$

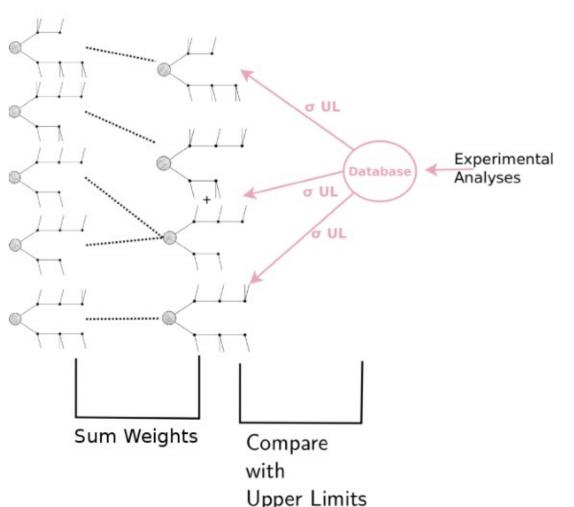

We (currently) ignore spin, color, etc of the BSM particles

It is model independent, there is no reference to the original model

Recap: How SModelS works

3) Comparison of predicted signal strengths with experimental result:

- **Upper Limit Results:** Predicted signal strength = σ x BR Experimental result: σ_{LII}
- Efficiency Map Results:

 Predicted signal strength = $\sum \sigma x BR x \epsilon$ Experimental result: $\sigma_{UL} = N_{UL} / L$ from $N_{observed}$, expected(BG), error(BG)
- \cdot r = predicted / σ_{UL}
- Model is excluded if most constraining analysis has r > 1
